Appendix I

The Theodore Transform: Inter-Axis Projection and Cross-Domain Transposition

This appendix names and formalizes an operation the manuscript has used throughout without naming it. The operation transfers information from one domain to the next, the way a Laplace transform carries a function from the time domain to the frequency domain: the object changes its representation, and the structure the representation carries stays fixed. Chapter 8 uses the operation to project the Haitian Theorem from the racial axis onto the gendered axis. Chapters 2–21 use the operation to transpose the entire social-mechanical framework into electrodynamics. This appendix defines the operator, states its invariance condition, works both uses on material already in the manuscript, and marks the limit of what the operator can establish.

Confidence tier. The formal apparatus of this appendix is Tier 3 (structural). It names and unifies moves the manuscript already executes and introduces no new calibrated measurement. Falsification criteria appear in Section I.6.

I.1 Domains, Vocabularies, and Correspondence Maps

Fix an indexed family of domains $\{D_\alpha\}_{\alpha \in A}$. Two index sets matter in this book. The first is the set of identity axes along which the Predatory Min-Max Function partitions the population: race, gender, sexuality, and the further axes Chapter 22 resolves into sub-bands. The second is the set of formal substrates across which the framework has been developed: social mechanics, circuit theory, thermodynamics, and control systems (Appendix G).

Each domain D_α carries a vocabulary $\mathcal{V}_\alpha$ (the symbols and defined quantities of that domain) and a claim set $\mathcal{C}_\alpha$ (the propositions statable in that vocabulary). On the racial axis the vocabulary includes $O_{\text{racialized}}$, F_{enforce}, the wage ψ, and the Enclosure Score $\mathcal{S}_{\text{enc}}$. On the gendered axis the vocabulary includes O_{gendered} (Equation 19.16), coverture, and the reproductive extraction kernel documented in Chapter 8.

Structural correspondence

A **structural correspondence** between domains D_α and D_β is a map $\sigma_{\alpha\beta} : \mathcal{V}_\alpha \to \mathcal{V}_\beta$ assigning each element of the source vocabulary its structural analogue in the target vocabulary: the element occupying the same position in the extraction topology $(E, P_{\text{uppet}}, F_{\text{enforce}}, I_{\text{buffer}}, O)$ and standing in the same relations to its neighbors.

The manuscript constructs such correspondences repeatedly and explicitly. $O_{\text{racialized}} \mapsto O_{\text{gendered}}$ maps the racialized Out-group to the gendered Out-group; both sets are defined by exclusion from lethal autonomy (Equation 9.1). The slave-patrol and carceral machinery of Chapter 9 maps to the gendered enforcement machinery of Chapter 8: coverture statutes, eugenics law, and the criminalization of pregnancy. The kinetic labor of $O_{\text{racialized}}$ and I_{buffer} maps to the power supply V_{cc} of the circuit model, and the psychological wage ψ_s maps to reactive power Q_{reactive} (Appendix H).

I.2 The Transform

The Theodore Transform

Let $\sigma_{\alpha\beta}$ be a structural correspondence. The **Theodore Transform** is the substitution operator

$$\dagger_{\alpha\to\beta} \; : \; \mathcal{C}_\alpha \; \longrightarrow \; \mathcal{C}_\beta, \qquad c \; \longmapsto \; \sigma_{\alpha\beta}(c), \tag{I.1}$$

where $\sigma_{\alpha\beta}(c)$ denotes the claim obtained by replacing every vocabulary element of c with its image under $\sigma_{\alpha\beta}$.

The operator carries a claim across domains the way the Laplace transform carries a function across representations. The input and the image differ in vocabulary. The image is legible exactly when the correspondence preserves the relations the claim asserts. The symbol $\dagger$ is reserved for this operator throughout the manuscript, consistent with the notation rule of Chapter 0: no other quantity in this book carries it.

I.3 The Invariance Condition

A claim asserted as a principle claims scope. A claimant who asserts a normative claim c on domain D_α as a principle commits to the transformed claim $\dagger_{\alpha\to\beta}(c)$ on every domain D_β inside the principle's scope. A claimant who asserts anti-racism as a principle thereby

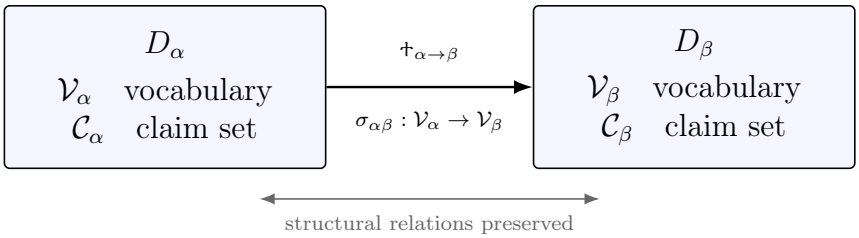

Figure I.1: **The Theodore Transform Operator.** This diagram renders the domain, vocabulary, claim-set, and structural-correspondence definitions of Section I.2 and introduces no new claim, measurement, or calibration.

asserts the image of that claim on the gendered axis, and on every other axis the principle covers. The transform converts that commitment into a checkable condition:

$$c \text{ holds on } D_\alpha \quad \Longrightarrow \quad \dagger_{\alpha\to\beta}(c) \text{ holds on } D_\beta \qquad \forall\, \beta \in S(c), \tag{I.2}$$

where $S(c)$ is the scope the claimant asserts. When Equation I.2 holds across $S(c)$, the claim is applied **invariantly**: it functions as a principle. When the equation fails at some $\beta \in S(c)$ and the claimant accepts the failure, the claim is applied **selectively**.

Theorem I.1 (Selective-Application Detection)**.** *Let a claimant assert $c \in \mathcal{C}_\alpha$ as a principle with scope $S(c)$, and let c hold on D_α. If $\dagger_{\alpha\to\beta}(c)$ fails on some D_β with $\beta \in S(c)$, and the claimant accepts the failure, then the claimant's operative commitment is a local rule of D_α: the asserted scope exceeds the honored scope.*

Argument. A principle is a claim together with its scope. The claimant asserts the pair $(c, S(c))$ and honors the pair $(c, \{\alpha\})$. The honored scope excludes β by hypothesis, so the honored scope is a proper subset of the asserted scope. The gap between the two scopes is the selective application. □

A failure of invariance licenses exactly one conclusion: the claim, as held by that claimant, functions selectively. Three further conclusions remain unavailable. First, the transform reports nothing about the truth of c on any domain: a claim can hold on every axis and still be applied selectively by a given claimant, and a claim can fail on every axis and still be applied invariantly. Second, the transform reports nothing about the direction of repair: invariance can be restored by extending c to D_β, by retracting c on D_α, or by shrinking the asserted scope, and the operator ranks none of these above the others. Third, the transform measures nothing: it introduces no quantity, no calibration, and no threshold. Its output is a scope audit of a claimant, stated in vocabulary the manuscript already supplies.

The operator therefore functions as an invariance test. It detects whether a claim is being applied as a principle. It establishes nothing about whether the claim deserves to be one.

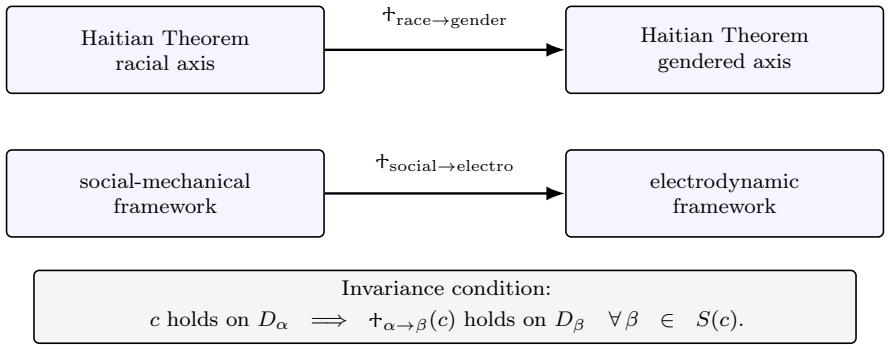

Figure I.2: **Two Applications of the Theodore Transform.** This diagram renders the inter-axis projection and cross-domain transposition stated in Sections I.4 and I.5, under the invariance condition of Equation I.2, and introduces no new claim, measurement, or calibration.

I.4 Use I: Inter-Axis Projection

The first use carries a claim from one axis of oppression to another and checks invariance. The diagnostic value sits in the asymmetry the check exposes: a claimant who accepts a claim on the gendered axis and rejects its image on the racial axis, or accepts it on the racial axis and rejects its image on the gendered axis, applies the claim selectively, and Theorem I.1 names the selectivity precisely.

I.4.1 Worked Example: The Haitian Theorem on the Gendered Axis

Chapter 19 states the Haitian Theorem (Definition 19.7, Equations 19.10 and 19.11): across the 1450–2026 dataset, structural liberation of the Out-group from the extraction kernel has been achieved exclusively through kinetic action. The theorem is established on the racial axis, with the Haitian Revolution as its anchor case.

Chapter 8 applies the Theodore Transform to this claim. The correspondence map runs as follows:

Source vocabulary (racial axis)	**Image vocabulary (gendered axis)**
$O_{\text{racialized}}$	O_{gendered} (Equation 19.16)
Slave patrols and the carceral apparatus (Chapter 9)	Coverture, eugenics statutes, and criminalized pregnancy (Chapter 8)
Disarmament of O (Chapter 18)	Gendered kinetic disarmament (Chapter 8)
Lethal Autonomy$(O) = 0$ (Equation 9.1)	Lethal Autonomy$(O_{\text{gendered}}) = 0$
Kinetic action	Kinetic action (fixed point of σ)

The image claim states: the gendered partition, installed and maintained through force, yields exclusively to force or to the credible, organized threat of force. Chapter 8 evaluates the image claim against the gendered dataset — the witch-hunts, the colonial dismantlement of the Agojie, the criminalization of indigenous gender systems, and the ongoing toll of intimate-partner violence — and records the result: the framework's conclusion for the gendered axis is identical to its conclusion for the racial axis, because the extraction kernel is identical. Equation I.2 holds for this pair of domains. The Haitian Theorem operates as a principle across the racial and gendered axes, and the gendered application of the theorem (withdrawal, deterrence, and the necessity of force) inherits the theorem's full force.

I.4.2 A Diagnostic Failure and What It Licensed

The manuscript also records a case in which a naive projection fails, and the failure does diagnostic work. Chapter 8 establishes that the intersection $O_{\text{racialized}} \cap O_{\text{gendered}}$ is transformative: the nature of the gendered wound changes depending on which side of the racial partition the woman occupies. A correspondence map that treats "women" as a monolithic Out-group produces image claims that fail on the racialized half of the set — the suffocation wound of the white feminine position and the devaluation wound of the Black feminine position diverge, and a claim calibrated to one misfires on the other.

The failure licensed a refinement of the correspondence, and the manuscript supplies the refined object: the bivector e_{14} of the Geometric Algebra extension (Equation E.6), a two-dimensional extraction plane qualitatively distinct from either axis alone. This is the correct reading of a failed invariance check under a coarse correspondence. The failure
